ACKNOWLEDGEMENTS

Completing a research project of the scope undertaken in this study is not feasible without the assistance of many individuals. I would like to acknowledge MAJ Rich Lann, Chief of Patient Administration at Silas B. Hays Hospital for his assistance and instruction in a variety of computer applications, and general encouragement throughout the study. I would also like to thank CPT Cathy Pickett and her entire Information Management Division staff for their encouragement, assistance with computer applications, and allowing me day, evening, and weekend use of their computer facilities. LTC A.J. Frelin of the Department of Nursing was extremely helpful in classification of CHAMPUS data and insight into the Workload Management System for Nurses.

A sincere thanks goes to Major Stu Baker of the Tri Service Working Group for providing the two primary databases in a timely manner, and for his counsel and advice for the project methodology.

A special thanks goes to two individuals from the Naval Postgraduate School, Monterey, California; LTC Jack Gafford for his time, frequent discussions on methods to approach the complex nature of hospital output, and his insight into the "art" of modeling. Dr. Richard E. Rosenthal, Associate Professor of Operations Research, provided immeasurable assistance in generating the model output, suggestions on methodologies to improve the validity of the model, and provided an introduction to the General Algebraic Modeling System.

Two other individuals were of significant assistance throughout the study period. MAJ Joe Wall of the Clinical Support Division at Silas B. Hays Hospital provided many ideas on possible approaches to the study methodology. I would also like to express a special thanks to my preceptor, LTC Mike Meyer for his encouragement throughout this year and allowing me the flexibility needed to complete the study.

INTRODUCTION

Conditions which prompted the study

Within the Army Medical Department, the current methodology utilized to describe the resources required for medical treatment facilities is based on workload performed and measured by number of admissions, patient census, outpatient clinic visits, and weighted ancillary procedures. The primary disadvantage of this methodology is none of these measurements address health care resource requirements as a function of patient case mix intensity. Hospital productivity for inpatient services is measured by the Medical Care Composite Unit (MCCU). For each patient admitted to an army treatment facility, the hospital receives 10 MCCUs workload value units plus an additional unit for each day of inpatient stay. The patient who requires intensive medical services receives the same workload value as a patient requiring minimal care. The implied assumption of this methodology is that all patients are basically homogeneous with respect to health care resources consumed. Other than each patient requiring some form of medical services, patients are generally not homogeneous. They present themselves with a variety of illnesses, possess significant variation in age and sex distribution, have wide cultural and race distributions, and require medical services on a continuum from low to high intensity.

It is interesting to consider where the incentive is for the military health care administrator with the current methodology. If only resource allocation goals are considered, the incentive is to provide services for those patient types who require minimal medical services and have a relatively short length of hospital stay. This approach allows for minimum health care resource expenditure and maximum resource allocation to the facility.

Patient classification systems based on patient case mix to determine health care costs and resource consumption is widely utilized in the health services industry today (Plomann et al, 1984). The basis for these classification systems is the more intense case types require more intense health care resource expenditures. With the advent of Diagnosis Related Groups (DRGs) and the Social Securities Amendments of 1983 (Public Law 98-21, Title VI), prospective payment for inpatient MEDICARE services based on the DRG patient classification system was established. Congress further expanded the use of DRGs to encompass Department of Defense health care facilities with the passage of the National Defense Authorization Act for Fiscal Year 1987 (Public Law 99-661). The specific language mandating utilization of the DRG patient classification system for military health care facilities states, "The Secretary of Defense after consultation with the other administering secretaries shall establish by regulation the use of Diagnosis Related Groups as the primary criteria for the allocation of resources to facilities of the uniformed services" (1986, sect 1101).

This legislation will have significant impact on military health care facilities. In contrast to the current methodology for health care resource allocation, providing low intensity services under a DRG resource allocation system will result in a reduced amount of resources allocated to the facility. There is an impetus for military facility commanders to know which types of patients will result in the largest amount of resources allocated for his/her facility. A model that could describe what services are producing the most significant intensity of outputs, with respect to input resources such as number of staff and number of beds available, could be of considerable value to hospital management. This model would theoretically describe which services provide the greatest degree of return on investment (input resources) given constraints on patient demand for a service and the total amount of service available. This model would also describe the consequences of variations in the demand for services, changes in personnel staffing, or the expansion or reduction of fixed resources. Since revenue generation for military health care organizations is generally not a goal, a more realistic goal for hospital management might be to maximize the quantity of health services delivered to the beneficiary population. Management may wish to determine the case mix of patients that would provide for the largest number of patients treated or to maximize some other measure of hospital output.

Hospital output consists of services provided in a variety of settings including ambulatory care, dental services, preventive medicine and wellness programs, ancillary services, and inpatient services.

The model developed for this study is limited to hospital output produced in the inpatient environment. The inpatient setting was selected to maintain the scope of the study to a manageable level and in an effort to account for a substantial portion of total hospital services produced.

Total inpatient output is defined as the weighted sum of the number of patients treated. The set of weights specified reflects the basic importance of each class of patient and the measure of hospital output is related to resource absorption. Each class in the weighted sum is defined in terms of the value of patients associated with a specific class. Note that this description of total inpatient output is not the equivalence of total number of patients treated. Rather, the goal of the model is to maximize the weighted sum of patients in terms of their value to the hospital.

PROBLEM STATEMENT

To develop a case mix model for maximizing the total output of inpatient workload for Silas B. Hays Army Community Hospital, Fort Ord, California.

OBJECTIVES

1. Conduct literature review.
2. Develop model.
3. Determine case mix groups.
4. Determine lower and upper bounds of patient demand for services.
5. Determine maximum amount of service available.
6. Validate model.
7. Develop management considerations and implications.

CRITERIA

1. The model will be able to determine the case mix which maximizes the total inpatient care provided.
2. The model will be able to measure the impact of changes to different case mix allocations given changes in patient demand for services, personnel staffing, and number of hospital beds.

ASSUMPTIONS

1. This model assumes linearity and constant returns to scale of resources used.
2. Quality of care will remain constant.
3. The patient case mix in future years will be similar to the case mix utilized in the study.

LIMITATIONS

1. Specific cost factors are not considered in the model. This would include factors such as cost per patient, and fixed costs.
2. Patient category priorities for care are not considered in the model. This includes patients by beneficiary categories such as active duty personnel, family members, and retired personnel. The implication of this limitation is the model may not reflect actual behavior of the organization. The model does not incorporate requirements to insure active duty service members receive services and other eligible beneficiaries when

resources are available. This facet was not considered in the model to keep the number of patient groups at a manageable level. The incorporation of patient beneficiary categories in the model would require 75 different patient classes as opposed to the 30 groups that were developed.

3. The upper demand for patient services does not account for eligible beneficiaries who received medical services under the MEDICARE program. The model accounts for potential patient demand by including beneficiaries who received inpatient services under the Civilian Health and Medical Program for the Uniformed Services (CHAMPUS). However, beneficiaries over 65 years of age are not eligible for CHAMPUS and normally receive care under MEDICARE benefits. This group may be significant both in terms of health care resource consumption and number of patients.
4. The model is limited to inpatient services provided.

Literature Review

The initial impetus in developing patient classification systems was due to concern over tremendous growth in health care costs, which by 1983 accounted for approximately 10.5% of the nations gross national product (Williams and Torrens, 1984). A significant amount of the initial research into patient classification systems was based on diagnostic grouping within the International Classification of Diseases (ICDA). Evans and Walker (1972) produced 98 groups based on ICDA and age/sex distributions.

Perhaps the most significant research effort in the development of patient classification systems was the Yale University study which resulted in the creation of Diagnosis Related Groups (DRGs) (Fetter et al, 1980). The primary purpose of the development of Diagnosis Related Groups was to produce a manageable, medically interpretable set of diagnostic groups that allow for differences in case complexity. Medically interpretable refers to the ability of physicians to relate to a specific class of patients and to identify a particular medical management path for them. Case complexity is described by age, primary and secondary diagnosis, and primary and secondary surgical procedure (Fetter et al, 1980).

Horn (1983) attempted to improve on Fetter's work by developing a severity of illness index within DRGs based on four levels of severity across seven dimensions. These dimensions included stage of primary diagnosis, complications, interactions, dependency, whether the patient had a non operative procedure, response rate to treatment and the

residual following therapy. By 1984, there were a variety of patient classification systems available within the health service industry (Plomann et al, 1984). The majority of these classification systems are based on the premise that health resource requirements are a function of patient case mix intensity.

Within the literature, a number of researchers have developed mathematical models based on case mix in an effort to examine the impact case mix has on hospital costs and resource consumption. Baligh and Laughunn (1969) developed a linear model where patients were divided into classes based on their "value" to the hospital, although they did not indicate how a health care facility would develop these values. The objective was to maximize the number of patients in each class subject to service availability, patient demand, budget constraints, policy constraints, and technology constraints. Goldfarb et al (1980) describe a linear model based on number of patients, case mix, quality of service, and revenues subject to constraints on the number of beds available.

Finally, Brandeau and Hopkins (1984) developed a linear model to examine the affect of changes in patient mix under existing and proposed reimbursement mechanisms on a large teaching hospital. The model specifically incorporated the costs, revenues, and resource consumption patterns associated with patients categorized into different intensity and payer groups. The model appears to be the only one in the literature which was actually implemented. This model was the basis for negotiating MEDICAID reimbursement rates for Stanford University Hospital in 1982 (Brandeau and Hopkins, 1984).

METHODOLOGY

The methodology for this project is divided into four primary sections:

1. Formulation of the linear model and selection of data sources.
2. Generating model output.
3. Model analysis.
4. Model Validation.

The Linear Model

The following variables are utilized in the formulation of the linear model:

i = the index for inpatient clinical services ($i=1,2,\dots,10$)

j = the index of classes of patients by intensity levels of low, medium and high ($j=1,\dots,3$)

k = location of patient wards and nursing personnel ($k=1,\dots,5$)

x_{ij} = the total number of patients type j in the i th service

c_{ij} = relative patient value for service i and type j patient

b_{ij} = the mean bed days used for service i and type j patient

b_{ik} = the location of patient beds used by service i

b_k = the total bed days available at patient ward k

l_{ij} = the minimum patient demand for patient type j associated with service i

u_{ij} = the maximum patient demand for patient type j associated with service i

n_{ij} = the average number of nursing hours required to treat patient type j associated with service i

n_{ik} = the location of nursing personnel used by service i

n_k = total nursing hours available for patient ward k

p_{ij} = the average number of physician hours required to treat
patient type j associated with service i

p_i = the total number of physician hours available for service i

The linear model can be expressed as follows:

Maximize the weighted sum of patients treated =

$$\sum_{i=1}^m \sum_{j=1}^n c_{ij} x_{ij}$$

Subject to:

$$\sum_{i=1}^m \sum_{j=1}^n b_{ik} b_{ij} x_{ij} \leq b_k \quad (\text{for all } i\text{'s and } k\text{'s}) \quad \text{Bed Constraint (s)}$$

$$l_{ij} \leq x_{ij} \leq u_{ij} \quad (\text{for all } i\text{'s}) \quad \text{Demand Constraint(s)}$$

$$\sum_{i=1}^m \sum_{j=1}^n n_{ik} n_{ij} x_{ij} \leq n_k \quad (\text{for all } i\text{'s and } k\text{'s}) \quad \text{Nursing Constraint(s)}$$

$$\sum_{j=1}^n p_{ij} x_{ij} \leq p_i \quad (\text{for all } i\text{'s}) \quad \text{Physician Constraint(s)}$$

All variables ≥ 0

Data sources

Data was obtained from the Tri-Service Performance Measurement Working Group, Clinical Investigation and Health Care Studies Division, Fort Sam Houston, Texas; Office of the Civilian Health and Medical Program for the Uniformed Services (OCHAMPUS), Denver, Colorado; and the Department of Nursing and Resource Management Division of Silas B. Hays Army Community Hospital, Fort Ord, California.

The data obtained from the Tri-Service Performance Measurement Working Group consisted of two databases. Database 1 consisted of all inpatients receiving services at Silas B. Hays Hospital during fiscal year 1986. The data depicts by DRG code the frequency or number of patients treated and mean bed days used. The complete database is at Appendix A and consists of over 900 entries. Database 2 consisted of the 1986 Health Care Financing Administration DRG codes, verbal description, and relative cost weights. At appendix B is the complete database and totals 473 entries. The two databases were obtained in a LOTUS 123 spreadsheet format.

In an effort to structure the two databases in a usable format for the study, a computer program was developed to consolidate the verbal descriptions into the Silas B. Hays database. Appendix C lists the program and Appendix D is the consolidated database utilized in the study.

A third database was obtained from OCHAMPUS consisting of all patients receiving inpatient medical services under CHAMPUS benefits during FY86 for the Fort Ord catchment area. The catchment area is considered to be a 40 mile radius around Fort Ord.

The Department of Nursing of Silas B. Hays Hospital provided data concerning average number of nursing staff by ward location during FY86. This data was extracted from two separate bi-annual summary reports of the Workload Management System for Nurses (1985)

The Resource Management Division of Silas B. Hays Hospital provided data consisting of total physician inpatient hours worked during FY86 by clinical service.

Formulation of the objective function:

Within the objective function, j = the index for classes of patients and x_{ij} = total number of patients of type j associated with clinical service i . The primary objective in developing these classes was to determine a level of resource consumption or level of intensity. These classes of patients were created so that no patient belongs to more than one class and no patient fails to belong to a class. That is, these classes are collectively exhaustive and mutually exclusive.

The patient classes were developed based on the relative weight value associated with each DRG. This value represents average hospital costs for a specific case type. Pettengill and Vertrees originally developed the cost weights which became the basis for prospective payment under the MEDICARE program (1982). Utilizing billed charges as well as cost information for over 5900 hospitals and almost 2 million patient dispositions, they developed relative cost weights to accurately reflect the average cost per case type that were solely attributed to differences in case mix (Pettengill and Vertrees, 1982). The relative weights range from .1136 to 12.3234. A value of 1.0 indicates hospital costs equal to

the average costs for all hospitals. A case type of 1.5 indicates expected costs equal to one and one half times the average hospital costs (Pettengill and Vertrees (1982)).

Three classes were developed consisting of low, medium, and high intensity patients. All patient types with a relative weight value of greater than one were classified into the high intensity patient class. Although somewhat arbitrary, the low and medium weight ranges were developed by summing the relative weights of the DRGs between .1136 and .9999 and dividing by total number of DRGs. The ranges and corresponding patient intensity level are indicated at Table 1.

PATIENT INTENSITY LEVEL AND
DRG RELATIVE WEIGHT CLASSIFICATION SCHEME

<u>PATIENT INTENSITY</u>	<u>RELATIVE WEIGHT RANGE</u>
LOW	.1136-.6598
MEDIUM	.6615-.9999
HIGH	1.0000-12.3234

Table 1. Table 1 describes the development of patient intensity levels based on DRG relative weight values (source: author, May 87).

Inpatient workload for FY86 was distributed among 14 different clinical services. To maintain a manageable number of total groups, Family Practice workload as well as some subspecialty service workload was consolidated into major clinical services. Table 2 depicts the ten services utilized in the study and the clinical services which were consolidated.

CONSOLIDATION OF INPATIENT WORKLOAD
SBHACH, FY86

MAJOR CLINICAL SERVICE	CONSOLIDATED SERVICES
Internal Medicine	Cardiology, Neurology, Dermatology, Family Practice Medicine
General Surgery	Family Practice General Surgery
Urology	Family Practice Urology
Gynecology	Family Practice Gynecology
Obstetrics	Family Practice Obstetrics
Pediatrics	Family Practice Pediatrics
Neonatal	Family Practice Neonatal
Orthopaedics	Family Practice Orthopaedics
Psychiatry	Family Practice Psychiatry
<u>EENT (eye/ear/nose/throat)</u>	<u>Family Practice EENT</u>

Table 2. Table 2 depicts the consolidation of FY86 inpatient workload for Silas B. Hays Army Community Hospital (source: author, May 87).

The c_{ij} values represent the relative patient value in the objective function and is expressed by the case mix index for the j th type patient and i th service. Since the model is designed to maximize, the higher the case mix index for a class of patients within a service, the more value the hospital will place on that group of patients. The case mix index was developed by multiplying the number of patients treated by the respective DRG relative weight value. The weighted products were then summed and divided by the total number of patients for all the DRGs. This process was followed for each intensity level and each clinical service. Table 3 depicts the coefficient values for the objective function. Appendix E describes the calculations for each clinical service and patient intensity level.

OBJECTIVE FUNCTION VALUES FOR THE
LINEAR PROGRAMMING MODEL

CLINICAL SERVICES	PATIENT INTENSITY LEVELS		
	LOW	MED	HIGH
INTMED	.5689	.7770	1.3505
GENSURG	.5397	.8448	1.8444
UROL	.5099	.8715	1.7441

OB	.3816	.7540	1.1486
PEDS	.5265	.7480	1.4929
NEONATAL	.2971	.6811	1.8296
ORTHO	.5291	.7404	1.1658
PSYCH	.5221	.7738	1.0729
EENT	.4409	.7943	2.1199

Table 3. Table 3 depicts the case mix indices for the linear programming model (source: author, May 87).

Formulation of Constraints

Bed Constraint

The measure of resource absorption for beds utilized by the various clinical services and classes of patients was developed by calculating the weighted mean of bed days utilized. The number of patients by DRG case type were multiplied by the mean bed days used per case type. The mean bed day products were summed and then divided by the total number of patients within the class. Table 4 depicts the weighted mean bed days used for each clinical service and patient intensity level. Calculations for this constraint can be found at Appendix E.

BED ABSORPTION FOR LINEAR MODEL

CLIN SERVICES	PATIENT INTENSITY LEVELS		
	LOW	MED	HIGH
INTMED	3.750	5.000	8.410
GENSURG	3.950	4.540	9.960
UROL	3.590	6.500	12.120
GYN	2.760	5.590	6.180
OB	3.000	4.250	7.140
PEDS	2.360	3.180	4.600
NEONATAL	3.510	0.820	3.590
ORTHO	3.830	4.810	7.960
PSYCH	6.150	7.390	65.580
EENT	2.210	3.730	8.140

Table 4. Table 4 show the weighted mean bed days used for each patient intensity level and clinical service during FY86 (source: author, May 87).

To determine the total number of beds available, the first step was to determine which patient wards were associated with specific clinical services. The Pediatric, Neonatal, Obstetrics, and Psychiatry services are associated with only one primary patient ward. The remaining clinical services utilize two patient wards interchangeably. There is a medical ward and surgical ward within the hospital consisting of 38 beds each. Patients may be placed on either unit contingent upon ward census and personnel staffing. Table 5 describes the patient wards associated with each clinical service.

PATIENT WARD AND
CLINICAL SERVICE ASSOCIATION

<u>CLINICAL SERVICE</u>	<u>TYPE WARD</u>
INT MED	Medical/Surgical
GEN SURG	Medical/Surgical
UROL	Medical/Surgical
GYN	Medical/Surgical
PEDS	Pediatric
OB	Obstetrics
NEONATAL	Neonatal
ORTHO	Medical/Surgical
PSYCH	Psychiatric
<u>EENT</u>	<u>Medical/Surgical</u>

Table 5. Table 5 describes the clinical service association with five types of wards at Silas B. Hays Army Community Hospital for FY86 (source: author May 87).

Table 6 is a matrix describing the association of clinical services to the five patient wards. The value of "1" is placed into the matrix where the association between bed location and clinical service exists to illustrate the mechanics of the linear model. If we assume all blanks in Table 6 are equal to 0, the constraint equation

$$\sum_{ij} b_{ik} b_{ij} x_{ij} \leq b_k$$

will only charge a clinical service for beds used when $b_{ik} = 1$.

MATRIX OF CLINICAL SERVICE AND
PATIENT WARD ASSOCIATION

CLIN SERVICES	PATIENT WARDS

PSYCH	40	14600

Table 7. Table 7 depicts the total number of beds available for Silas B. Hays Army Community Hospital for FY 86 (source: author, May 87).

Demand Constraint

The minimum demand level by patient class (l_{ij}) is developed based on the premise that each service requires a certain minimum amount of workload for teaching purposes and to maintain medical proficiency. This constraint was developed by soliciting expert opinion from selected members of the clinical staff. Each service chief for clinical services utilized in the study group was provided a listing of patient data for his or her clinical service during FY86. This patient data was extracted from Appendix E and consisted of all data relevant to the specific clinical service. The service chief was asked to make a recommendation of the minimum number of patients required to maintain medical proficiency and for teaching purposes. Table 8 depicts the lower bound of patient demand as estimated by the clinical chiefs.

CLIN SERVICES	MINIMUM DEMAND LEVELS		
	PATIENT INTENSITY LEVELS		
	LOW	MED	HIGH
INTMED	200	300	75
GEN SURG	146	125	70
UROL	135	75	35
GYN	175	120	30
OB	920	290	120
PEDS	372	185	34
NEONATAL	920	28	30
ORTHO	22	41	19
PSYCH	10	10	8
EENT	256	20	6

Table 8. Table 8 depicts the minimum workload estimated by the clinical service chiefs based on FY86 DRG data (source: author, May 87).

The upper limit on patient demand was calculated utilizing the number of patients treated at Silas B. Hays Hospital during FY86 plus a quantity of unmet demand as extracted from CHAMPUS data. Reports were obtained from OCHAMPUS which depict, by primary diagnosis and number of patients, beneficiaries receiving inpatient medical service under CHAMPUS benefits during FY86 for the Fort Ord catchment area. These patients were classified into the patient intensity levels and clinical services. Seventy five patients who required a clinical service that is not within the mission of the hospital were not included in the classification. This includes patients requiring neurosurgical, vascular

surgery, and intensive neonatal clinical services among others. The classification was done by the nursing supervisor for medical/surgical services at Silas B. Hays Hospital. This individual was selected due to her willingness to participate in the study and clinical nursing experience of more than twenty years. Since the CHAMPUS data could not be obtained in a DRG format, the classifications were based on a subjective assessment by the nursing supervisor.

There were a total of 742 patients who received inpatient services under the CHAMPUS program during FY86. This number accounts for 7.7% of the total demand for inpatient services for the Fort Ord catchment area. Recall, however, the total patient demand does not account for eligible beneficiaries who received medical services under MEDICARE benefits.

Table 9 describes the number of patients receiving medical services at Silas B. Hays Hospital, under CHAMPUS benefits, and total patient demand.

Personnel Constraints

The physician and nursing estimates of resource absorption were developed by soliciting expert opinion from selected members of the physician and nursing staff. For the physician estimate, each clinical service chief was provided a descriptive listing of all case types treated during FY86 from Appendix E for his or her clinical service. He/she was asked to make an assessment of the mean time required to treat an average patient within each intensity level based on three different parameters; the least amount of time required, the most pessimistic time required, and the most probable time required. The measurement was expressed in hours and a weighted mean estimate was developed based on the following formula.

$$\text{(LEAST TIME REQ} + 4 \text{ (MOST PROBABLE TIME REQ) + (MOST PESSIMISTIC TIME REQ) / 6}$$

For the nursing resource estimate, the same data from Appendix E was provided to the nursing supervisor for medical, surgical, psychiatric services and the nursing supervisor for obstetrics, gynecology, pediatrics, and neonatal services. The two supervisors were asked to make the estimates in the manner described for physician estimates, but for nursing hours required for an average patient. Table 10 and 11 describe the estimates of physician and nursing resource absorption.

Table 11. Table 11 describes the estimated nursing hours required to treat an average patient case type (source: author, May 87).

Since physicians are associated with a specific clinical service (i), and nurses with a specific type ward (k), the total amount of available time for these two constraints was developed from different sources. The maximum amount of physician time available during FY86 was based on data extracted from the Uniform Chart of Account for Personnel Utilization System (UCAPERS). This is a workload and time reporting system utilized in all uniformed services health care facilities. Physicians are required bi-annually to make estimates of what percent of their time is devoted to inpatient care. The surveys from January and June 86 were utilized for the study and a mean estimate was calculated from the two survey estimates. Each physician is also required to account for the total number of hours worked each month. For each physician providing inpatient services, these monthly hours were summed for the period of October 85 through September 86. The total monthly hours were multiplied by the mean percent of time spent providing

inpatient services per physician. Once the fiscal year total inpatient hours were calculated for each physician, these values were summed by clinical service to determine the total amount of physician hours available for inpatient services.

Since workload hours are reported by each of the 14 different clinical services, the Family Practice and sub specialty services were consolidated into the ten services utilized in the study. Table 12 depicts the estimated physician hours available for inpatient services for each clinical service and total consolidated hours available.

Table 12. Table 12 depicts the estimated amount of available physician hours for inpatient services by clinical specialty (author, May 87).

The amount of total nursing time available was developed from two-biannual reports from the Workload Management System for Nursing (WMSN). The WMSN is a patient acuity model designed to estimate nurse staffing requirements. The two reports utilized in the study are ward specific and include mean daily number of nursing personnel available for duty in a 24 hour period. A weighted mean number of nursing personnel was calculated for these two reports and for each type ward. Nursing personnel on the medical, surgical, and intensive care units were combined to create one patient ward type called Med Surg. Since nursing personnel are only available eight hours a day, the mean number of nursing personnel available for a 24 hour period was divided by 3. This value was multiplied by 365 days for the year and again by 24 to determine the total number of hours available. Table 13 lists the nursing hours limits by type of patient ward.

Table 13. Table 13 depicts the estimated amount of available nursing hours for inpatient services by patient ward (author, May 87).

Generating Model Output/ Model Analysis

Model output was generated utilizing the General Algebraic Modeling System (GAMS) developed by Brooks, Druid, and Meeraus of the World Bank (1987). Assistance in generating the output was provided by Dr. Richard E. Rosenthal, Associate Professor of Operations Research, Naval Postgraduate School, Monterey, California.

The model was successful at producing a feasible/optimal solution. That is, there were no unbounded constraints or infeasible constraints within the model. The model generated a weighted sum of patients treated of 4079 and total number of patients allocated to the various patient groups of 6651. At Appendix F are the results of the initial generation of output. Table 14 shows a comparison of the number of patients generated by the model and the minimum/maximum constraint bounds. The marginal column provides an indication of the costs or profits in relative terms of the addition of another patient in a given patient group.

EENT	.HIGH	6.0000	7.0000	7.0000	2.1199

Table 14. Table 14 shows a comparison of the number of patients generated by the model and the minimum/maximum constraint bounds (source: GAMS output, Jun 87).

From table 14, the highest cost incurred (\$7.09) is for the addition of another high intensity psychiatric patient. This appears to be logical considering the model indicates an average high intensity psychiatric patient requires approximately 65 bed days, 100 hours of physician resources, and 138 hours of nursing resources. On the other hand, the addition of a high intensity EENT patient will result in a relative profit of \$2.12.

Further analysis of the initial output indicates that physician hour limits appear to inhibit the model from allocating additional patients. Table 15 compares the amount of physician hours used and the total amount of physician hours available.

PHYSICIAN RESOURCE UTILIZED

EENT	-INF	1215.523	1668.000	.

Table 15. Table 15 compares the amount of physician hours used and the total amount of physician hours available (source: GAMS output, Jun 87).

The internal medicine, general surgery, obstetrics, orthopaedic and psychiatry services utilized all available physician hours. The model directs all other clinical services to provide services for the maximum patient demand. Further inspection of table 15 reveals additional hours available for the pediatric, neonatal, gynecology, urology, and EENT services.

Since the same set of physicians provide services for OB/GYN and Pediatrics/Neonatal services, the total hours available for these two services were merged and a second iteration of model output was generated. The results are listed at Appendix G. The second iteration

produced a weighted sum of patient of 4299 compared to the initial output of 4079 and total patients allocated increased from 6651 to 7233 for a net gain of 582 patients. Table 16 lists the comparison of number of patients allocated by the model and the minimum/maximum patient demand bounds.

Table 17. Table 17 describes the physician hours absorbed by the merging of total available hours for the OB/GYN and Peds/Neonatal services (source: GAMS output, Jun 87).

One of the primary goals of this model is to describe which clinical services and patient intensity levels are producing the most significant intensity of outputs. The model does accomplish this, but the degree of magnitude is inhibited to some extent by the minimum patient bounds established for teaching purposes and to maintain medical proficiency. In an effort to develop some indication of which patient types are producing the largest degree of outputs, a third iteration was of the model was generated without any minimum patient demand. This iteration produced a weighted sum of patients of 4522 and total number of patients allocated to the various groups of 7423. Table 18 describes the comparison of the number of patients allocated by the model and the maximum patient demand. The output for this iteration is at Appendix H.

Table 18. Table 18 describes the comparison of the number of patients allocated by the model and the maximum patient demand (source: GAMS output, Jun 87).

Inspection of table 18 reveals the model made no allocation of patients for the internal medicine medium class, general surgery medium, orthopaedic low, and psychiatric high intensity patients. Of the remaining 26 patient classes, the model allocated the maximum demand to 22 services and patient intensity levels. The purpose of this exercise is simply to provide an indication of which groups of patients are most profitable or expensive without the constraint of minimum demand levels.

An analysis of the remaining constraint sets indicates that nursing nor bed days utilized were a factor in the number of patients allocated by the model. Table 19 and 20 are extracted from Appendix G and provide a comparison of nursing and bed day resources utilized by the model and total resources available.

Table 19 shows the nursing resource absorption and total available nursing hours for the five ward types. Forty two percent of the total nursing hours available were utilized. The implication of this is nursing personnel within the hospital are idle approximately 58% of the time, which does not seem rational. There is a high probability that nursing hours required for a typical case type have been underestimated, the total amount of nursing hours available are overestimated, or a combination of both.

Model Validation

The model can be validated utilizing criteria developed for mathematical models as described by Giordono and Weir (1985).

1. Does the model answer the problem statement?
2. Is the model usable in a practical sense? That is, can the data to operate the model actually be gathered?
3. Does the model make common sense?

The model developed in this study allocated patients based on the most optimal case mix and resource absorption patterns of the various patient classes. Patient classes were weighted based on their value to the hospital. More value was placed on the higher intensity patients than lower intensity patients. The model has described the consequences of variations in physician hours available and changes in patient demand for services. There was an attempt to develop the objective function and estimates for the resources absorbed by the various patients groups

in a rational manner and utilizing data available in a military health care facility and other DOD agencies. However, the model can only be considered valid based on the assumptions of the behavior being measured, the accuracy of the estimates formulated, and its' limitations.

Concerning the accuracy of resources absorbed, it appears the nursing constraint set was not accurate. From an intuitive perspective, one would expect nursing resources to impact on the hospitals' ability to provide services to a more significant degree than the model output indicates.

For the physician and bed resources used by the model, these estimates can be compared to actual number of patients treated and the total number of bed days used during FY86 in an effort to provide an indication of validity. The second iteration of model output (Appendix G) allocated a total number of patients of 7233 and total bed days used of 28587. The actual performance of the hospital for FY86 was 8135 inpatients and total bed days used of 41037. A ratio of number of patients to bed days used can be calculated for the model output and actual hospital performance for FY86. The model output produces a ratio of .2530 (7233/28587) versus the actual hospital performance for FY86 of .1982 (8135/41037). The ratio of the model output is within 5.5% of the actual FY86 performance ($.2530 - .1982 = .548$) for the bed resources utilized. This would appear to be a reasonably valid estimate.

Considering that 8135 inpatients received services in FY86, it would seem reasonable to expect the model to allocate approximately the same number of patients. The second iteration of model output allocated 7233 patients. Since physician hours available were inhibiting the model from allocating additional patients, a fourth iteration of model output was generated increasing the total number of physician hours for each service by 50% and the results of this output generation is at Appendix I. This resulted in the model allocating a total of 8407 patients. The physician hours utilized for this output iteration is at table 21. One could speculate that the physician resource absorption, total hours available, or a combination of both vary from actual physician behavior by 30-40 percent. Overall, the physician constraint set seems to be moderately underestimated.

PHYSICIAN RESOURCE UTILIZATION

Table 21. Table 21 describes the physician resources utilized with a 50% increase factor for available hours (source: GAMS output, Jun 87).

Management Considerations

The inpatient case mix allocation model can be a useful tool for hospital management in evaluating future health care delivery alternatives for the Fort Ord beneficiary population. The environment of the uniformed services delivery system is dynamic and parallels the civilian health services industry. There are a number of initiatives ongoing which will affect the health care delivery at Silas B. Hays Hospital. The hospital administration is presently negotiating with the Veterans Administration for shared services and planning for the implementation of two ambulatory care clinics under the Primary Care for the Uniformed Services (PRIMUS) program. The PRIMUS clinic is a contractual agreement between the hospital commander and a health care delivery contractor to provide primary care services to a segment of the local beneficiary population. There are also congressional initiatives to reform the CHAMPUS program. The implications of sharing agreements, contracting of primary care, and CHAMPUS reform are opportunities for the military health facility commander to evaluate and select from a variety of management alternatives. The model developed will provide the commander an indication of which services and patient types should be allocated to the military health care facility and to the civilian health care sector.

Although a definitive methodology for uniformed services health resource allocation has not been developed at this time, the model will allow for alteration of the objective function coefficients once the DOD resource allocation methodology has been developed. Given that the allocation of health care resources will utilize Diagnosis Related

Groups, the use of DRG case mix indices within the objective function in this study seems to be appropriate.

The model should be utilized as an adjunct to other management information systems within the hospital, and from the perspective of its' assumptions and limitations. Additionally, the refinement of the nursing and physician resource parameters will improve the usefulness of the model.

Conclusions and Recommendations

A case mix allocation model was developed which allocates patients to various clinical services and patient intensity levels based on the value of various patient groups and their resource consumption patterns. The problem statement, objectives and criteria of the study have been met given the assumptions and limitations of the model. The model has potential to be a useful management tool for future inpatient allocation issues.

The model is a foundation which can be built upon to improve its' usefulness to management. Future research efforts should include refinement of the resource consumption estimates and limits. Physician and Nursing consumption patterns within the various patient groups could be measured by selecting a representative sample of DRGs within the various patient groups. Audit and concurrent measurement of physician hours reported may improve the accuracy of the physician hours limits. The addition of patient beneficiary categories may improve the ability of the model to reflect actual hospital behavior. A methodology to capture eligible beneficiaries receiving services under MEDICARE benefits would

also enhance the accuracy of the model. One approach might be a survey of retired personnel in the Fort Ord catchment area

There are contributions and costs associated with other activities within the hospital, which could be added into the model. Radiology, pathology services, and supply costs are consumed by the various patient groups at different rates. Measurement of these consumption patterns would provide the model with a further degree of refinement.

With the advent of a DRG based resource allocation methodology for military treatment facilities, management must understand how different patient types are consuming the available resources and the consequences to the health care resources allocated for the facility. There is an impetus to know which patient types will result in the best form of reimbursement for the facility. In military health care facilities, this takes the form of personnel allocation and budget. The case mix model is a practical first step to achieve a better understanding of these issues.

APPENDIX J

ABBREVIATIONS AND DEFINITIONS

ALOS: Average Length of Hospital stay.

ALOS PROD: The value obtained by multiplying the average length of hospital stay by the frequency or number of patients within a DRG case type.

Case Mix: The relative proportion of the different types of cases a hospital treats. . Case mix measures are calculated by application of a set of weights to the number of patients falling into each case type within a hospital (Fetter et al, 1980).

Case Mix Index: The value obtained by dividing the DRG Weighted Product Sum by the total number of patients treated.

CC: Complications (Found in Appendix B, D, and E.)

Clinical service abbreviations:

INT MED	Internal Medicine
GENSURG or GEN SURG	General Surgery
UROL	Urology
GYN	Gynecology
OB	Obstetrics
PEDS	Pediatrics
ORTHO	Orthopaedics
PSYCH	Psychiatry
EENT	Eye, Ear, Nose, and Throat

APPENDIX J

ABBREVIATIONS AND DEFINITIONS (cont)

CLSVC or CLIN SERVICE: Clinical service

Diagnosis Related Group (DRGs): A patient classification scheme that identifies in the hospital acute care setting a set of case types, each representing a class of patients with similar processes of care and a predictable utilization of services (Fetter et al, 1980)

DRG Relative Weight (REL WGT): The decimal value attributed to each DRG. Each DRG receives a distinct weight that represents the relative hospital resource utilization on an average case.

DRG Weighted Product (WGT PROD): The value obtained by multiplying the number of patients treated and the DRG Relative Weight.

DRG Weighted Product Sum: The value obtained by summing the DRG Weighted Products.

FREQ: Frequency or number of patients receiving medical services.

WGT ALOS: A weighted length of hospital stay per DRG case type.

W/O: Without. (Found in Appendix B,D, and E.)
